Summer mortality
of Pacific oyster
Crassostrea gigas

The Morest Project

This sample, taken in early September 2002 on the Auray study site, shows the first phenotypic differentiation observed between resistant oysters (above), which had spawned in July, and susceptible oysters (below), which had developed gonads but did not spawn this year.

Acknowledgements

This work could not have been completed without the support of the regions of Basse-Normandie, Bretagne, Pays de la Loire and Poitou-Charentes; the Conseil général du Calvados and European funding from the IFOP via the CNC (Comité national de la conchyliculture). We thank them for their concerted effort that was decisive for the success of our activities.

This support completed our funding needs by adding to those allocated to us by Ifremer, who we also thank for the decision to put this project into action, bringing together numerous teams and laboratories, and for providing financial support until the end of the project. In particular, we thank Jean-François Minster, managing director of Ifremer at the time of the project and Maurice Héral, the scientific director.

Apart from the skills and facilities available at the different Ifremer laboratories, we thank the directors of the other institutes in France where we found complementary expertise. This meant that several specialists from the CNRS, universities at Nantes, Montpellier and Brest, Muséum national d'histoire naturelle at Concarneau and Institut Pasteur in Paris were largely involved in the project.

The Morest collaboration also allowed close working contact with regional and departmental structures for the transfer of research to the industry. We particularly thank Smel, Smidap, Creaa and Sysaaf for their efficient contributions to the fieldwork and the interaction they maintained with the industry.

We also thank the Comité national de la conchyliculture (CNC) who followed this work closely throughout the project and who raised many relevant questions about the research, generating fruitful scientific and technical debate. The Sections régionales conchylicoles (SRC), and their presidents and secretaries also played an essential role by establishing exchanges with the industry at the regional level. We truly appreciated their initiatives in encouraging this dialogue for which we are very grateful. We, therefore, thank the whole of the shellfish industry for their actions and support in the fieldwork, and their reflection and help with obtaining funding.

As coordinator, I warmly thank all of the scientific and technical participants who agreed to involve themselves in this challenge, to have continued throughout the duration of the project and to have participated actively in the pluridisciplinary

construction of the programs and their realization. They can be congratulated for having been part of this scientific and technical challenge that was also a great human experience. Thank you for the pleasure of working together.

On behalf of all the Morest partners,

J.-F. Samain,
Coordinator

Preface	XIX
1. Evaluation of summer mortality risk factors in shellfish farming ecosystems	1
Introduction	1
Monitoring bivalve mortalities at the national level	2
A historical analysis of oyster mortalities in France.....	2
Mortalities in the Morest study sites.....	5
Objectives of chapter 1.....	9
The thermal risk factor	9
Thermal characteristics of the study sites.....	9
Thermal dynamics and mortalities.....	11
Summary.....	15
The pluviometric risk factor	15
Pluviometric results at the national scale	16
Pluviometric results at the Morest study sites.....	18
Summary.....	26
The trophic risk factor	26
Relationship between mortality and trophic resources (quantitative aspect).....	27
Relationship between mortality and trophic resources (qualitative aspect)	36
Summary.....	40
The sediment risk factor	41
The sedimentary risk in the study sites.....	42
Studies on the chemistry of the sediment in the study sites	46
Summary.....	49
Discussion–conclusion	50
Spatial and temporal variability of the environmental risks under study	50
The thermal risk.....	51
The pluviometric risk	52

The trophic risk.....	55
The sedimentary risk	57
Analysis of a combined environmental risk.....	59
2. Mortality risks associated with physiological traits of oysters during reproduction.....	63
Introduction	63
Materials and methods.....	64
Experiments performed under controlled conditions	64
Field experiments.....	66
Live material.....	66
Analytical methods	68
Gametogenesis, nutrition and mortalities	68
Metabolic needs in summer.....	71
Evolution in metabolic needs with changes in temperature	71
Evolution of metabolic needs during gametogenesis	71
The use of reserves over the summer period	74
Use of reserves at different temperatures	74
The use of reserves depending on the intensity of gametogenesis	76
The effect of age on use of reserves.....	78
Annual variation in glycogen enzymes.....	79
Reserves and mortality	80
Conclusions on reserve utilization	81
Nutrition and energy balance during summer	82
Analysis in controlled conditions	83
Field studies.....	85
Modeling energetic fluxes over gametogenesis.....	87
Immune deficiency in summer	94
Oyster hemocytes: multipurpose cells	94
Hemocyte parameters and temperature.....	95
Hemocyte parameters and reproduction.....	97
General conclusion	105
3. Oyster summer mortality risks associated with environmental stress.....	107
Introduction	107
Experimental stress studies.....	109
Effect of hypoxia.....	109
Effect of pesticides.....	117
Sources of disturbance and environmental stress examined with the 'bottom-rack' comparison model.....	120
Potential sources of toxicity from the sediment	121
Potential toxicity sources in water and quality of the nutritional environment	127
Relationships between distance from the sediment and stress in oysters in the 'bottom-rack' experimental model	138
Conclusion.....	150

4. The genetic basis of summer mortality in Pacific oyster spat and potential for improving survival by selective breeding in France.....	153
PART I. Study of the genetic basis of summer mortality resistance in juvenile Pacific oyster <i>Crassostrea gigas</i> over four generations of selection	153
Introduction: context and objectives	153
First generation: estimation of the genetic basis of spat survival in their first summer in the field.....	155
Materials and methods	155
Results from the first generation.....	158
Second generation: divergent selection for high and low survival of spat in their first summer in the field	160
Materials and methods	160
Results	162
Third generation: repeatability of the response to divergent selection for high or low spat survival in the first summer and expression of the character in triploids	164
Production of the G3 batches.....	164
Field study results.....	165
Fourth generation: repeatability of response to selection.....	167
G4 production.....	167
Studies on the G4 batches	169
Field survival performances in the second summer period.....	170
Survival of batches that spent two summers in the field	171
Survival of batches that spent their first summer in the nursery and their second summer in the field	172
Laboratory studies of spat survival performance and correlations with field data	172
Results of the laboratory experiments.....	172
Comparisons between mortalities in the field and the laboratory.....	174
Discussion and prospects for future research.....	175
Genetic basis vs. vertical transmission of a pathogenic agent?.....	178
Why is there so much genetic variation for resistance to summer mortalities in natural populations?.....	178
Prospects for future research.....	179
PART II. Towards Gigas+, a selection program to improve summer survival of the Pacific oyster <i>Crassostrea gigas</i> in France	179
A review of the use of selection methods for shellfish improvement worldwide	179
Introduction.....	179
The French shellfish industry	180
Genetic improvement methods used in France.....	181
Commercial selection programs.....	182
Points for the creation of a collaborative selection program to improve oyster summer survival in France: Gigas+	190
Objectives of Gigas+	190

Advantages and limiting factors of the Gigas+ selection program	192
Conclusions	193
Appendix: Summary list of Morest generations and batches studied.....	194
5. Phenotypic characteristics of ‘R’ and ‘S’ oyster lines, selected for resistance or susceptibility to summer mortality	197
Introduction	197
Differences in gametogenesis and reproductive effort between R and S oysters	198
Gametogenesis at the spat stage.....	198
Gametogenesis at 18 months	199
Comparative energy balance of R and S oysters	204
Energy supply within the animal: energy components	205
Comparative measurements of carbohydrate pathways during the critical period preceding mortalities.....	207
Defense capacities of R and S oysters	209
Materials and methods.....	209
The genetic basis of hemocyte parameters.....	210
Hemocyte parameters in R and S oysters.....	210
Stress responses of R and S oysters	221
Experimental study of the adaptation mechanisms of R and S oysters in conditions of hypoxia and pesticide exposure.....	221
Effect of pesticide exposure on the use of energy	224
Environmental stress associated with gametogenic effort in R and S oysters	227
Aneuploidy levels of R and S oysters.....	228
R and S oyster responses to pathogenic agents	230
Bacterial infections	230
Herpes virus status of R and S stocks	232
Conclusion on the role of pathogens in the mortality of R and S stocks.....	233
Differential gene expression between R and S oysters and the identification of physiological functions conferring resistance to summer mortality.....	234
Differential gene expression in natural conditions before a mortality episode	234
Differential gene expression under experimental conditions and the study of risk factors	236
General discussion and conclusion	239
6. Oyster summer mortality risks associated with pathogens	243
Introduction	243
Finding and identifying potential candidate pathogens.....	245
Repamo-Morest: abnormal <i>Crassostrea gigas</i> mortalities declared between 2001 and 2005.....	245

<i>Vibrio</i> bacteria found in oysters during mortality episodes (2001–2004) in hatcheries and oyster parcs	252
Taxonomic characterization of bacterial isolates	255
Development of specific diagnosis tools.....	258
Pathogenicity and conditions of expression of infection.....	260
Bacteria and reproduction of mortalities in the laboratory	260
OsHV-1 virus, infection and transmission.....	270
The search for bacterial virulence genes.....	272
Strains of <i>Vibrio aestuarianus</i>	272
Virulence factors in strains of the <i>Vibrio splendidus</i> group.....	275
Pathogenic agents and risk definition.....	278
Temporal variation of <i>Vibrionaceae</i> flora in oysters and the marine environment	278
Ecology of <i>Vibrio aestuarianus</i>	282
Conclusion	285
7. Temperature as a risk factor in oyster summer mortality.....	289
Introduction	289
Oyster physiology	290
Gametogenic stages and 19°C.....	290
Spawning and 19°C	292
Energy balance and 19°C	292
Respiration	295
Hemocyte parameters and temperature	297
The sediment and 19°C	298
Sediment remineralization and 19°C.....	298
Diffusion and temperature	300
Sediment effects and partial spawning	302
Genetics and temperature	302
Pathogens and temperature.....	303
What influence does temperature have on bacteria?.....	303
What influence does temperature have on herpes virus OsHV-1?.....	304
General conclusion.....	305
8. A synthesis of the Morest project and recommendations for forecasting and managing oyster summer mortalities.....	307
Introduction	307
PART I. Analysis of summer mortality using an interaction model	308
Seawater temperature.....	309
Reproduction.....	309
The stage of reproductive development.....	309
Reproductive effort	309
Food level	309
Oyster age.....	310
Oyster genetics.....	310
Stress.....	310

Distance from the sediment.....	310
Freshwater releases in full summer.....	311
Annual freshwater inputs.....	311
Other stresses.....	311
Conclusion on the risk factors of the interaction model.....	311
PART II. Risk management.....	312
Temperature risk.....	312
Risks associated with the 19°C temperature threshold.....	312
Thermal dynamics and mortality risks in the first and second years....	315
Reduction of mortality risks in the first year (first summer).....	316
Rearing on sites where the temperature is lower than 19°C.....	316
Trophic limitation at the spat stage.....	316
Risk reduction by increasing the distance from the sediment.....	319
Discussion and conclusion.....	324
Reduction of mortality risks in the second year (second summer).....	325
Rich trophic environments: reducing reproductive effort	
by livestock transfers.....	325
Discussion and conclusion.....	331
Less rich environments.....	332
Exploitation of genetic variability.....	332
Purging of naturally collected spat.....	332
Selection of resistant oysters.....	334
Triploid oysters.....	335
Discussion and conclusion.....	336
PART III. Risk forecasting methods.....	336
Forecasting risk timing.....	336
Forecasting the scale of mortality risk.....	336
The pluviometric effect.....	336
The development of forecasting methods.....	341
Models.....	341
New instruments: real-time monitoring probes.....	346
Discussion and conclusion.....	348
References.....	349
